

AI-assisted Minimum Qualifications (MQ) and Relevant Experience Pilot

Module 6 Task 1: AI Adoption Initiative Design Canvas

Section 1 — Problem Statement

Minimum qualification (MQ) and relevant experience reviews can vary by analyst, especially for complex resumes, with inconsistent documentation and limited bias checks. This creates uneven outcomes and makes decisions harder to explain. An AI-assisted MQ and relevant experience review pilot can improve consistency, documentation, and fairness while keeping final decisions human.

Section 2 — Target Audience

The primary audience is Compensation staff, including Compensation Analysts and the Compensation Manager. Their current AI fluency is about 1–2 out of 5, meaning most have limited experience beyond basic chat use. They need a practical, easy-to-follow workflow that fits existing resume review work and helps with complex MQ and relevant experience assessments. A likely concern is that AI may create extra work, produce unreliable outputs, or feel risky in a high-stakes HR context. This initiative builds directly on my Module 3 Workflow Audit Matrix, which identified MQ and relevant-experience review as a top AI-integration candidate because it is time-intensive, cognitively demanding, and well suited to a centaur-style workflow in which AI drafts structured analysis and humans retain judgment and final authority.

Section 3 — AI Tools and Approach

This initiative will pilot two versions of the same workflow. The first uses U of A GenAI with Claude Sonnet 4.6 through Open WebUI; its modality is text-based AI, and the rationale is that it provides an institutionally governed environment for structured resume-to-job-description review. Resume data is high sensitivity, job descriptions from JDXpert are low sensitivity, and the system prompt is medium sensitivity; use must follow unit and institutional AI rules.

The second version uses a Python/Streamlit application that calls Claude Sonnet 4.6 through an API. Its modality is code plus text AI, and the rationale is to create a more structured interface, support side-by-side comparison with U of A GenAI, and align the project with Python-based AI workflow development. This version handles the same high-sensitivity resume data and should be used only in an authorized pilot setting until broader approval is established.

Section 4 — Ethical Safeguards

A major risk is exposure of sensitive applicant or employee data, so the safeguard is to use controlled pilot conditions, follow the Compensation AI guideline, and keep final records and decisions in HR systems rather than the AI tools. Another risk is algorithmic bias in MQ or relevant experience analysis; safeguards include human review of every output, fairness checks on sample cases, and documentation of overrides when analysts disagree with the draft analysis.

A third risk is over-reliance on AI in high-stakes decisions, so the project explicitly treats AI output as draft analysis only, not as a final decision. A fourth risk is scope creep, so the workflow is limited to MQ and relevant experience review support unless Compensation leadership authorizes additional use cases. Responsibility for these safeguards rests with the Compensation Manager, participating analysts, and any required HR/IT reviewer.

The pilot also aligns with the NIST AI RMF and University of Arizona Responsible AI guidance by pairing institutionally governed tools with defined human verification, documentation, and scope limits for high-sensitivity HR work.

Section 5 — Equity Considerations

One group that may face higher risk is applicants with non-traditional career paths, such as career breaks, caregiving histories, international experience, or unusual job titles. The adjustment is to include prompt instructions in both workflow versions that explicitly consider equivalent experience and non-linear career paths, while requiring analysts to manually review and document edge cases.

A second group is analysts with lower confidence using AI or a Python/Streamlit interface. The adjustment is to provide both workflow versions during the pilot, offer short written guidance and hands-on support, and let analysts compare which interface is easier and more trustworthy for their work. A third equity concern is that repeated runs may produce small differences in fractional years of experience; those should not be treated as errors when both runs round to the same whole-year result under current normal practice.

Section 6 — Success Metrics

Success will be measured first by consistency of MQ and relevant experience conclusions across analysts and across the two workflow versions. This will be assessed through a pilot comparison of analyst-only review, U of A GenAI-assisted review, and Python/Streamlit-assisted review, with a minimum acceptable threshold of at least a 10 percentage-point improvement in agreement or a documented reduction in unexplained variation.

Success will also be measured by documentation quality, workflow usability, and result stability across both versions. At least 90% of pilot cases should include complete documentation of inputs, AI use, and human verification; analyst usefulness ratings should average at least 4 out of 5; and at least 85% of cases run in both systems should show no material change in the final substantive conclusion after human review. Time impact may still be tracked for complex cases, but only as a secondary metric rather than the main success claim.

Section 7 — Rollout Plan — First Three Steps

Step 1 is to finalize the revised U of A GenAI prompt and update the Python/Streamlit application so both versions use the same input documents, output structure, and review logic. This step will be completed by me, with review from one senior Compensation analyst, using existing U of A GenAI

access, Claude API access, sample resumes, and JDXpert job descriptions, within two weeks of course completion.

Step 2 is to run an AI-assisted MQ and relevant experience review pilot using a small set of resumes and job descriptions, asking analysts to use both versions when feasible and record which they prefer, why, and whether the result materially changed.

Step 3 is to prepare a short summary for the Compensation Manager showing pilot findings, including consistency, documentation quality, analyst preference, and whether one workflow should move forward or whether both should remain available. This step will use the pilot data, analyst feedback, and the unit AI guideline, and should be completed by week 6.

50-Word Elevator Pitch

This AI-assisted MQ and relevant experience review pilot in Compensation uses both U of A GenAI and a Python/Streamlit app with Claude Sonnet 4.6. The goal is to improve consistency, documentation, and fairness in complex resume reviews while keeping all final MQ and relevant experience decisions under human control.
